

DISPENSER FOR HIGHLY VISCOUS LIQUIDS AND PASTES • JOLLY FIELDS IZOE

BACKGROUND OF THE INVENTION

The present invention relates to a throw-away dispenser with leverage to precisely control amount of highly viscous liquids and pastes dispensed, with provision to remove air from container on initial filling by manufacturer, to preserve the integrity of the product by keeping air away from product until dispensed, to maintain a clean nozzle tip, to stop flow of product after actuator knob is released, to dispense virtually all product from dispenser.

There are a large number of dispensers available which are useful to dispense such products as mayonnaise, catsup, mustard, and the like, as well as toothpaste and other products. In conventional containers for dispensing these viscous liquids, the product within the dispenser becomes exposed to air once the seal is broken and some of the contents are dispensed. Moisture in the air above the product condenses when the dispenser is placed in the refrigerator for storage between uses thereby depositing water on the product. Dispensers placed on counters in fast food and other restaurants represent an unsanitary condition due to ambient air coming into contact with the liquid within the dispenser. There are no inexpensive throw-away dispensers available which have leverage to dispense highly viscous products as caulking and peanut butter.

A number of patents have been issued which disclose dispensers of viscous liquids.

USP 3,999,691 discloses a cake filler dispensing apparatus for semi-fluid material having a housing with a vertical bore and a second bore with a piston connecting with this vertical bore. APPARATUS IS COMPLICATED IN STRUCTURE.

USP 4,050,612 shows a dispensing container for flowable materials such as creams - includes a pair of opened ended containers nested telespecially with a piston in the upper container. DISPENSER IS INCONVENIENT TO USE AND DOES NOT ALLOW PRECISE DISPENSING OF PRODUCT.

USP 4,154,371 is a dispensing container with a piston forming the bottom of the container with a compressible container, lying in front of the piston and having a mouthpiece. Expelling of the product from the mouthpiece would have a vacuum effect to pull the piston upward. LEVERAGE TO PULL PRODUCT TO ORFICE IS LIMITED.

USP 4,323,177 shows an injection piston for use in cylindrical dispensing containers or packages of the type containing viscous or plastic masses such as sealing compounds or adhesives. Ejection pressure is used to increase the effective diameter of the piston top to seal air from product during ejection. PISTON PRESSURE BY COMPRESSED AIR IS COMPLICATED AND INCONVENIENT.

USP 4,479,592 describes a dispenser for providing measured amounts of a paste in which actuator is depressed down. Piston casing cannot move down because of the gripping action of a reed spring clip. When actuator is released, spring clip pushes piston upward to dispense measured amount. LEVERAGE IS LIMITED TO STRENGTH OF SPRING CLIP. DOES NOT PROVIDE COMPLETE SEALING OF PRODUCT.

USP 4,767,032 has a dispenser with a hollow dispensing tube reciprocating within the container which incrementally moves a piston downward for forcing paste upward. Ratchet has outward projecting spring with tangs to grip the smooth inner cylinder. LEVERAGE IS MINIMAL. DOES NOT MAINTAIN A CLEAN EJECTION TIP.

USP 4,886,186 discloses a dispenser for the delivery of dosed amounts of a pasty substance having a push button mounted on the receptacle for movement upwardly and downwardly adjacent an end thereof. A toothed rod extends through the receptacle and is connected at its inner end to a follower plunger. Upward movement of plunger is effected either by vacuum or a spring. LEVERAGE IS WEAK. SEALING IS INEFFECTIVE.

USP 5,170,913 shows a container with a discharge outlet and a pliant tubular wall. Squeezing of pliant tubular wall expels product. A piston follower has seals that slide on inner wall to prevent entry of air into product. SQUEEZING OF PLIANT TUBE WOULD NOT EXERT ENOUGH FORCE TO ASSURE PISTON FOLLOWER WOULD SLIDE INSIDE PLIANT TUBE.

USP 5,547,107 shows a dispenser for flowable materials which includes an outer barrel telescoped over a sealable plunger. Moving outer barrel down forces product out spout in barrel. NO LEVERAGE ADVANTAGE. PROBLEM IN MAINTAINING CONCENTRICITY.

USP 5,720,416 has a dispenser for viscous liquids in which two vane blades rotate to close out on two stationary walls in circular chamber with the ability to dispense two products simultaneously. THERE IS NO LEVERAGE ADVANTAGE AS KNOB ROTATING VANE BLADES MOVES SAME AMOUNT AS VANE BLADES.

USP 6,655,557 B2 describes a dispensing device for dispensing a viscous product as a cream or gel. Top of device has outer threads that are manually rotated through inner threads of container to force out product. DEVICE WOULD BE HARD TO ROTATE AND DIFFICULT TO MANUFACTURE.

None of the above patents teaches the present invention.

• Summary of the Invention •

This invention provides a throw-away dispenser with leverage to precisely control amount of product dispensed for highly viscous liquids and pastes as caulking, peanut butter and viscous products as mayonnaise, glues, paints, etc.

Nozzle section has ability to expel air from dispenser on initial packaging by manufacturer, to keep air away from product until dispensed and to expel virtually all product within container, and is inexpensive to manufacture.

A dispenser for highly viscous liquids and pastes in which a hollow cylinder is provided with a threaded hub at one end. Vent holes on top of cylinder allows sealant as paraffin to be placed above "O" ring seal for longer shelf life.

Inside top of knob sleeve is attached to top of threaded actuator rod. Rotation of knob has knob sleeve rotating around and down cylinder outer circumference wall.

Actuator rod threads downward through cylinder threaded hub - rotating actuator rod spindle and disk inside ram bottom wells. This action moves ram toward nozzle opening - without rotating ram.

Actuator spindle bottom touches ram bottom well - slightly before disk bottom wall touches ram well. This centers downward force at center of ram. Spindle vertical wall - rotating in ram bottom well; and disk horizontal wall - rotating in upper ram well - prevent ram from tilting - to assure smooth downward movement to precisely control amount dispensed.

After cylinder is filled with product, nozzle section locks into and seals open end of cylinder from inside, outside and bottom. Nozzle bottom simultaneously moves up in cylinder bottom to force product to nozzle tip and remove virtually all air from container.

Nozzle tip is provided with a valve that concaves upward. Valve has four slits that create four flaps. Valve wall at center of slits is thinner and progressively becomes thicker toward outer circumference.

Flaps open under pressure when knob is rotated and close when knob is released. Flaps open small amount for less viscous products and more for highly viscous products to automatically compensate for viscosity of product.

Both P6 nozzle cap and P12 small dual nozzle cap are designed to clean nozzle inner tip and push valve back to original position to prevent sticking.

Product can be dispensed over a period of time without the need for a nozzle cap to prevent leakage.

Nozzle section placed into bracket has nozzle tip pointing down. Knob placed in bracket has nozzle tip pointing up. Nozzle saucer with hex center hole can be placed over hex nozzle tip and rotated to pump products - as artists' paints lotions, bean - cheese dips, etc. - into saucer.

Knob sleeve can be placed in horizontal position. Products that have oil rising to top - such as natural peanut butter would have oil automatically integrated into mixture with nozzle section-cylinder rotating - with knob locked in bracket.

It is thus a principal object of this invention to provide an inexpensive, convenient, efficient and effective apparatus for the dispensing of highly viscous liquids as caulking and peanut butter as well as a large number of food, medical and industrial products, to keep air away from product, to control amount dispensed, to close off air after dispensing action, to dispense all product and maintain a clean nozzle tip.

Ram bottom is same configuration as nozzle section. At extreme bottom product close-out, ram completely fills up nozzle section - to expel virtually all of the product from container.

Other objects and advantages of this invention will hereinafter become obvious from the following detailed description of preferred embodiments of this invention.

BRIEF DESCRIPTION OF THE DRAWINGS

The following figures illustrate preferred embodiments of the dispenser of this invention:

Fig. 1 is perspective view of the the preferred embodiment of assembled parts of invention with dispenser in empty position - knob sleeve locked in bracket - with P12 small dual nozzle cap on nozzle tip with nozzle cleaner inside tip - especially convenient for commercial and industrial use in dispensing caulking, glue, paint, etc.

Fig. 2 is perspective view of the preferred embodiment of assembled parts of invention with dispenser in fill position - nozzle section locked in bracket - P6 nozzle cap locked into nozzle section - appropriate for dispensing viscous and highly viscous products as caulking, peanut butter - as well as cosmetic pastes, lotions, mustard, catsup, medical products and thousands of other products.

Fig. 3 is perspective view of preferred embodiment of assembled parts of invention with dispenser in empty position - knob sleeve locked in bracket - with P11 nozzle saucer attached to nozzle tip - appropriate for pumping viscous and highly viscous products as artists' paints, lotions, bean - cheese dips into saucer.

DESCRIPTION OF THE PREFERRED EMBODIMENTS

Referring to Figs. 1-19, dispenser comprises P1 cylinder to hold product. P3 actuator rod **33a-33b** is threaded up through bottom inside cylinder hub **14b-14a**. Actuator rod flange **35** goes against cylinder hub bottom **15** to prevent actuator rod being threaded out of cylinder hub **14b-14a** by consumer.

When P4 ram is in initial product - filled position, ram top wall **41** is against cylinder top inner wall **11a**. Cylinder center hub **14b** with internal threads comes down inside cylinder to be against actuator rod flange top **35**. Bottom of flange **35** is even with P4 Ram dished out center **45b-46a**. This provides cylinder hub **14a-14b** the maximum rigidity to keep actuator threaded rod in concentricity - as knob rotates actuator rod - to move ram down to dispense product.

P9 lock ring must be inserted over cylinder hub end before P2 knob sleeve is placed over cylinder. Knob sleeve top well flats **24a, 24b** slide over actuator top two flats **32a, 32b** to lock actuator to knob.

Assembly is set with knob down - open cylinder end up. Ram is inserted in open end of cylinder with ram well **46a-46b** over actuator disk **36** and ram well **47a-47b** over actuator spindle **37**.

P8 "O" ring seal inner wall **82** is forced over ram side wall **43-42**. This brings "O" ring seal outer wall **81** into compression against cylinder inner wall almost to top of cylinder. This allows maximum size of "O" ring seal and a greater compression factor than conventional methods - that lock seal in at both top and bottom. "O" ring seal will compress down as much as needed to prevent lock-up. This arrangement allows a more versatile and better seal to compensate for draft and molding variation.

Cylinder is filled with product. P5 nozzle section inner wall **52a-52b** is inserted over cylinder outer wall at **11b**. Nozzle section projections **53a, 53b, 53c** are rotated over cylinder tabs **16a, 16b, 16c** to lock nozzle section to cylinder. Cylinder bottom wall circumference at **11b-12b** has radius to give slightly when pressured against nozzle section inner wall **56a** for more effective sealing.

Nozzle circular sleeve **51** goes inside cylinder wall **12b** to provide further seal. Simultaneously, nozzle inner horizontal wall **56a** moves up inside cylinder to force product into and possibly even through P7 molded rubber close-off valve - locked into nozzle section at **57a-57b** - and through nozzle tip orifice at **58a-58b**. This expels virtually all air from nozzle tip before inserting tamper-proof seal (not shown) over nozzle end **59**.

Lock ring openings **91a, 91b, 91c** are placed over nozzle section projections **53a, 53 b, 53c**. Lock ring walls **93a, 93b, 93c** are pressed into space between nozzle section projections **53a, 53b, 53c**. This prevents nozzle section from being rotated out of cylinder and provides neater appearance. Cylinder and nozzle section could be sonic-welded together.

Assembly line could have positioning holes for actuator rods to be placed into - if desired to place sealant - as paraffin through cylinder vent holes **13a** or **13b**. Sealant would be pressured into one vent hole and would go into space above "O" ring seal and between ram top wall **41**. Air would be expelled through opposite vent hole until paraffin comes out opposite vent hole. Knob sleeve would then be placed over actuator top.

Some items may require tamper -proof seal - in which case P12 small dual nozzle cap with hex **122a-122b** would firmly fit over nozzle end hex **59** with tamper-proof seal already attached. Other end **121b** of small dual nozzle cap has projection **123b-123a** to go inside nozzle tip for cleaning of products and push close-off valve back to original position.

Consumer can receive amount of product desired by amount knob is rotated. Actuator rod **33b-33a** threads through cylinder hub **14a-14b**. Actuator spindle bottom **38** touches ram bottom well **47b** slightly before actuator disk bottom wall **36** makes contact with ram well at **46b-47a**. Downward push of actuator is concentrated at the very center of ram to assure the ultimate equalization of downward pressure on ram.

Spindle vertical wall **37**- rotating in lower ram well **47a-47b** and actuator disk bottom horizontal wall **36** rotating in ram upper well **46b-47a** - prevent ram from tilting to assure smooth downward movement.

In event ram did tilt slightly - actuator spindle horizontal bottom wall **38** - rotating against ram well bottom **47b** and actuator disk horizontal bottom wall **36** - rotating against ram horizontal wall **46b-47a** - would push ram into alignment- to maintain concentricity of ram - to move ram smoothly toward nozzle end to expel product. Action does not rotate ram but forces ram toward nozzle tip. Actuator rod has holes **34a...34b** cored to save plastic and provide rigidity.

On initial assembly, close-off valve outer wall **71a-71b** is press-fit into nozzle section tip **57a** - and positioned at bottom by nozzle section ledge **57b**. Close-off valve has four slits from center **77a-77b** to: **73a-73b, 74a-74b, 75a-75b, 76a-76b** - which create four flaps.

Spherical roof wall is concaved upward and becomes progressively thicker from center **77a-77b** to outer circumference of the four flaps. A small amount of product is retained in nozzle section orifice **58a-58b** to keep air away from valve section. Both P6 or P12 nozzle cap can clean nozzle inner tip and push valve back to original position.

Less viscous products as mustard and honey would not require as much pressure to flow through the four flaps and would not open the four flaps as wide - when ejecting product through nozzle tip orifice **58a-58b**. The greater pressure to eject highly viscous products as caulking and peanut butter would open the four flaps wider.

The high leverage of the threaded screw rod going through cylinder threaded hub is essential for the close-off valve to operate in the above described manner. Spherical roof wall with four flaps can be of heavier construction - giving the four flaps greater ability to snap back to original position.

When knob is rotated, flaps open under product pressure - and close when knob and pressure is released. The four flaps snapping back to original position - pull excess product at nozzle tip back inside container - to keep nozzle tip clean and prevent products as caulking and glue from sticking.

P6 regular nozzle cap has center projection **63a-63b**. P12 small dual nozzle cap has center projection **123b-123a**. These two center projections clean nozzle tip and push close-off valve back to original position - in event valve ever stuck - as with caulking or glue.

Ram section **43-44-49** has same configuration as nozzle section **51 - 55a - 55b to 57a**. At extreme bottom, ram fills up space in nozzle section to eject virtually all product. Ram hollow center **48a-48b** is cored to save plastic.

In order to make knob sleeve grooves **22a-22b** the same diameter as nozzle section grooves **54a-54b**, knob sleeve has three vertical inner projections **23a, 23b, 23c** to serve as bearings against cylinder outside wall circumference **11a-11b**. With this arrangement, any knob sleeve groove **22a-22b** or nozzle section groove **54a-54b** will slide into and down to bracket circular ledge **105** - being prevented from rotating by groove locking into center vertical rib **104**.

With nozzle section locked into bracket, nozzle section tip would point down. With knob sleeve locked into bracket, nozzle section tip would point up. Nozzle saucer has hex center hole **113a-113b** to slide over nozzle section tip hex outer wall **59**. Nozzle saucer hex center hole **113a** would be level with nozzle section tip hex outer wall **59**. Reservoir **112a** receives product. Curved notches **111** on saucer

circumference are designed to make cleaning easier for consumer. Nozzle saucer can be slide on and off by consumer. Nozzle saucer or nozzle section can be rotated to pump products as artists' paints, lotions, bean - cheese dips into nozzle saucer. Rotating nozzle saucer with knob stationary - is the same as rotating knob sleeve with nozzle section and cylinder stationary.

Bracket can be attached with double-stick adhesive or screws through slots 101... for convenient use in bathroom, kitchen, shop. Two vertical holes 102 are provided to hold tooth brushes or small industrial items.

It is thus seen - there has been provided a dispenser for viscous and highly viscous liquids and pastes - which is highly effective in keeping product out of contact with air - to maintain integrity of product - after initial opening by consumer. Close-off valve automatically closes on releasing of knob to conveniently maintain a clean nozzle tip. Design of close-off valve automatically compensates for viscosity of liquids and pastes. With ram filling up nozzle section at extreme close-out, virtually all product is ejected from dispenser.

Nozzle cap - in coordination with close-out valve and nozzle orifice keeps products as caulking and glues from sticking in bottom of nozzle orifice. Dispenser is economical to manufacture, assemble and fill and is extremely versatile and convenient for usage in a tremendous number of products.

Knob sleeve can be locked in bracket or other accessory with nozzle section and cylinder in horizontal position. Products that have oil rising to top - as natural peanut butter would have oil automatically integrated into mixture as nozzle section and cylinder rotate on each dispensing action.

While only preferred embodiments of this invention have been described, it is understood that many variations are possible without departing from the principles of this invention as defined in the claims which follow.
